Abstract. The records of *Rhinolophus euryale* at the northernmost margin of its range in southern Slovakia and northern Hungary represent isolated spots of the species occurrence and together with the parts of the species range in Romania and Serbia are associated with the Carpathian mountain system. We revised distribution status of *R. euryale* in this mountain range and gathered more than 1600 records, both published and original. Five more or less isolated groups of records within the Carpathian range, bounded by 43–48° N and 18–23° E, have been recognised: (1) Southern Carpathians (NE Serbia and SW Romania), (2) Transylvania (W Romania), (3) Bükkvidék Region (N Hungary), (4) Gemer-Turňa / Görmör-Torna Region (S Slovakia and N Hungary) and (5) Dunazug-hegyvidék Region (NW Hungary), being separated from each other by river valleys, high mountains or mountains without extensive karst areas, and/or by the Pannonian Lowland. Analysis of roost types showed that attics of buildings nowadays represent 26.3% of all known roosts of nursery colonies; hence, in the Carpathian region *R. euryale* uses a more diversified roosting strategy compared to the remaining parts of the species distribution range. The evidenced distances of movements were rather small (range 0.5–16.7 km), suggesting sedentary character of the local Carpathian populations. Considering these results, based on evaluation of the banding data and on the data from simultaneous censuses (both summer and winter colonies) in some parts of this range (Slovakia, Hungary), we estimate the abundance of *R. euryale* in the whole Carpathian system at some 30,000 individuals only.

Faunistics, roosts, recovery, banding data, Hungary, Romania, Serbia, Slovakia

Introduction

The Mediterranean horseshoe bat, *Rhinolophus euryale* Blasius, 1853, is a typical bat of the thermo-Mediterranean zone of Europe. The species is distributed from northwestern Africa through most of southern Europe to the Middle East and the Caucasus. Southern and eastern limits of its distribution range lie in the Levant and Iran (Ibáñez 1999, Horáček et al. 2000, Gaisler 2001). The northernmost margin of its range is found in southern Slovakia and northern Hungary, where isolated populations occur in separate karst areas (Uhrin et al. 1996a, Boldogh 2007d, Hanák et al. 2010). To these Central European parts of *R. euryale* range, the closest areas of the species occurrence are present in Romania and Serbia (Fig. 1), all these patches of distribution are associated with the Carpathian mountain system. Romanian and Serbian spots of this range are represented by populations directly connected to the continuous south-European parts of the species range in the Balkans and Dalmatia (Gaisler 2001).

The Mediterranean horseshoe bat is considered a species under risk, with conservation status evaluated as near threatened or vulnerable on the global level (Hutson et al. 2001, Temple & Terry 2009). An evidence of population decrease has been observed in some parts of Europe; this is perhaps due to a high level of human pressure (e.g. Brosset et al. 1988). In the Carpathian part of its range, *R. euryale* was evaluated as a rare species with only a limited abundance (e.g. Topál 1954, 1969). The only exception is the occurrence in Serbia, the species is considered to be common in suitable regions of this country (Paunović & Stamenković 1998). Anyway, the species is listed among the most threatened mammals in almost all countries of its distribution range (Stollmann et al. 1997, Báldi et al. 2001, Witkowski et al. 2003, Paunović et al. 2004, Murrariu 2005). However, e.g. in Slovakia, no remarkable trend of long-term decrease in population numbers has been observed in the last years (Uhrin et al. 2010). In contrast to this evaluation, some marginal sub-populations in Hungary have been considered decreasing in the local scale and under a high risk of extinction (Boldogh 2007a, d, Paulovics & Juhász 2008). In addition, in the northern part of the Carpathian range, original roost preferences have been documented in maternity colonies, which occupy rather man-made structures (house attics) than natural roosts (caves); this suggests a certain shift in roost selection in the particular populations (see Horáček & Zima 1979). Considering these facts, a revision of distribution range of *R. euryale* in the Carpathian region is thus urgently needed.

A detailed review of *Rhinolophus euryale* occurrence in the Carpathian region has been provided only for Slovakia so far (Uhrin et al. 1996a). Although the data were quite intensively gathered also in all other Carpathian countries, their reviews remained unpublished (e.g. Paunović 2001, Paunović et al. 2004, Szodoray-Parádi et al. 2002). However, these data were used as a basis for several publications generally presenting outlines of the species range with the help of various square mapping approaches on both European and national levels (Valenciu 1993, Ibáñez 1999, Boldogh 2007d, Hanák et al. 2010, Uhrin et al. 2012). In the last several years, a significant number of new records of *R. euryale* has been gathered, enabling us to define precisely the pattern of distribution of this bat in its Carpathian range. This paper presents a summary of the occurrence of *R. euryale* in this unique promontory from the continuous range in the Mediterranean. Such account can naturally give an opportunity to analyse possible intrinsic trends in these populations, which will be presented in a subsequent study.

Material and Methods

All available data, both published and original, on the occurrence of *Rhinolophus euryale* in four countries of its Carpathian range (Slovakia, Hungary, Romania, Serbia) were gathered; these records cover the period from before 1859 till 2012

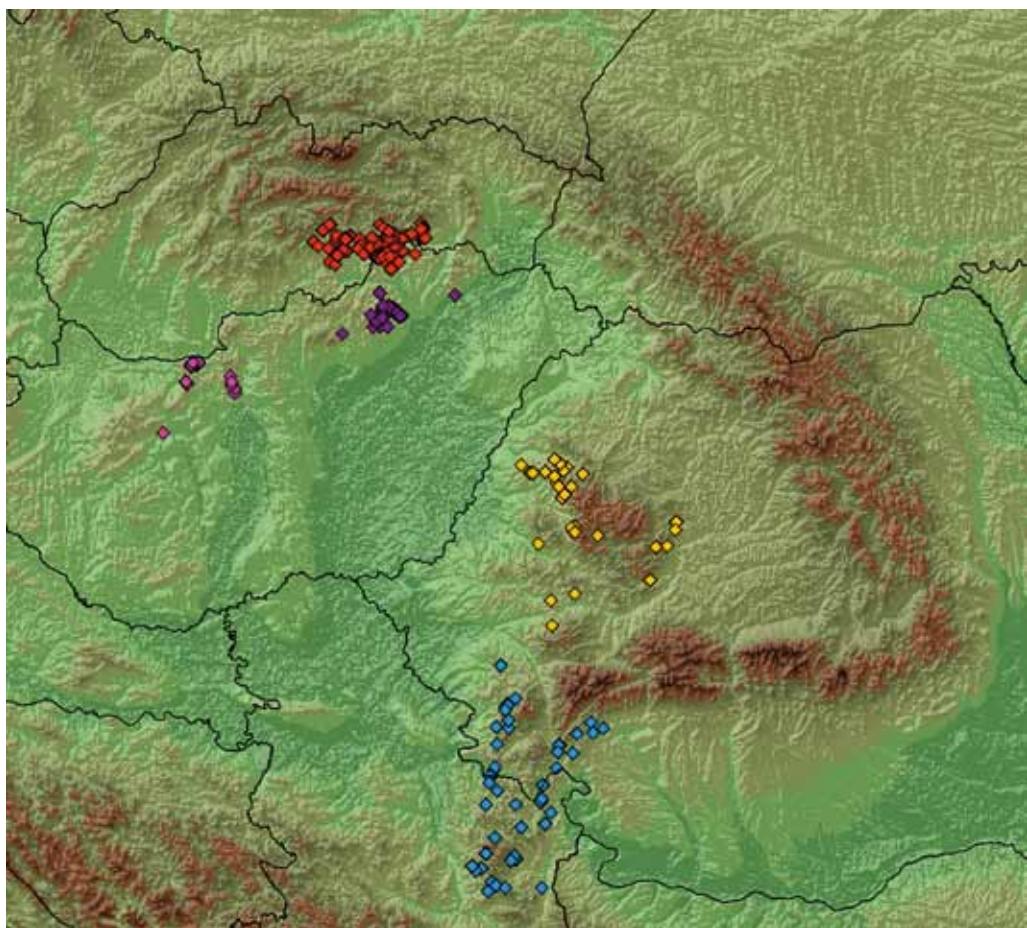

Fig. 1. Map of records of *Rhinolophus euryale* in the Carpathian region. Southern Carpathians – blue, Transylvania – light orange, Bükkvidék Region – violet, Gemer-Turňa / Gömör-Torna Region – red, Dunazug-hegyvidék Region – pink. For detailed description of regional groups of records see text in chapter General Patterns of Distribution.

(see Appendix). Field data were collected applying common bat research techniques, e.g. inspections of potential roosts (lofts, mines, and caves), nettings of bats in various habitats (mainly at the entrances to roosts) and using bat detectors. In the whole range under study, echolocation parameters of the species described from the core of the species range (e.g. Russo & Jones 2002, Papadatou et al. 2008) were used for evaluation of the recorded calls. Besides these approaches, some records of the species originate also from the analysis of owl pellets.

The complete database comprises more than 1,600 records of *R. euryale* (see Table 1). All records of *R. euryale* were set to coordinates in the World Geodetic System (wgs84) and visualised in the Quantum GIS (2012) software environment using free spatial data available at DIVA-GIS (<http://www.diva-gis.org>). To estimate extent of the species range in particular regions (Fig. 1, Table 2), a minimum convex polygon was calculated in Quantum GIS.

Results and Discussion

General pattern of distribution

Despite the great number of new records gathered for this account, these data did not change considerably the general extent of the distribution of *Rhinolophus euryale* in areas at the northern margin of the species range in Central Europe, as summarized earlier by Ibáñez (1999) and Gaisler (2001). However, the presented data enable us to describe the patterns of its occurrence in more details. The Carpathian range of the species is clearly restricted to the warmest parts of the mountain system, covering solely the inner edges of the arch of the Carpathian chain. Geographically, the records were made in three sub-provinces of the mountain system, the Serbian Carpathians, Romanian Western Carpathians and the Inner Western Carpathians (Král 2001; Fig. 1). The records were made solely in the hilly areas of the region (Fig. 16) and the species has never been recorded in lowland landscapes; with most probability, *R. euryale* penetrates neither westward to the lowland Pannonia, nor eastward to the Danube basin of Romanian Walachia. In the neighbouring Bulgaria, the species does not approach closely the Danube River and records at lower altitudes are rather scarce (Benda et al. 2003). It also seems likely that the species does not inhabit the basins in the Transylvanian Plateau and does not occur in the highest parts of mountain ranges within the delineated range (e.g. the Bucegi, Făgăraş, Parâng, Retezat, and Godeanu Mts. in the Southern Carpathians and elevated parts of the Bihor, Gilău or the Vlădeasa Mts. in Romania or in the rather elevated positions of the Slovenské rudohorie Mts. [Slovak Ore Mts.] in central Slovakia). Generally, there are no obvious differences between summer and winter ranges of the species in the respective regions (Fig. 2).

All records of *R. euryale* documented in the region could be divided into five groups rather isolated from each other; only one of them is situated outside the proper Carpathian mountain system. These groups of localities are separated from each other by large river valleys (Timiş, Mureş, Slaná/Sajó rivers), high mountains (Semenic, Cernei, Tarcu, Godeanu Mts.), rather low mountains without extensive limestone/karst areas providing suitable roosts (Cserhát and Mátra Mts.) and mainly by the vast Pannonian Lowland (Fig. 1).

Map of summer and winter records of *Rhinolophus euryale* in the Carpathian region. a – nursery colonies with more than 30 individuals (caves – yellow diamonds, mines – pink diamonds, buildings – blue diamonds) are shown in the map of other summer records (black diamonds). b – hibernacula with more than 100 individuals (light green diamonds) are shown in the map of other winter records (black diamonds).

Southern Carpathians. The southernmost group of the Carpathian records of *R. euryale* comes from northeastern Serbia and southwestern Romania; this area continues to the core range of the species in the Balkans (Gaisler 2001). Among the registered records, the sites situated most southward within the Carpathian system lie in the Rтанj and Tupižnica Mts. (ca. $43^{\circ} 47'$ N; Serbia), on the southern geographical/geological border of the Serbian Carpathians (Marković 1980). The species was recorded in the Romanian part of Banat already in the 19th century, the records are available from the Peștera Gaura cu Muscă cave (Kolenati 1860, Méhely 1900). This roost is contemporarily used both as a hibernaculum and a nursery of *R. euryale* together with several other bat species (max. 400 individuals; Nagy & Postawa 2010). The record sites are situated in limestone mountain ranges covered by deciduous forests on both sides of the Iron Gate gorge of the Danube (= Porțile de Fier / Đerdapska klisura; Figs. 1, 2; Paunović & Stamenković 1998, Nagy & Postawa 2010). Most of the records have been documented in the Kučajske planine Mts., Šomrda Mts., and the Miroč Mts. in Serbia, as well as in the Locvei and Aninei Mts. in Romania. The region is rather limited in its area (some 13,000 km²; Table 2) with about 60–100 km in the maximum longitudinal extent. The easternmost sites in this region are situated in Romania, on the southern slopes of the Southern Carpathians and are represented by both winter and summer roosts in caves (the Peștera Bulba, Peștera Lazului, and the Peștera Fușteica caves; ca. $22^{\circ} 54'$ N). The northernmost roost in Banat (Peștera Padina Matei cave, ca. $45^{\circ} 30'$ N) is also the site lying most closely to the agricultural landscape of Pannonia (ca. $21^{\circ} 48'$ E). *R. euryale* still remains unknown from the whole Serbian part of Banat (Vršački breg Mts.) and from quite a large area in

Table 2. Range area (ra), number of sites (s), density of sites (s-d) and estimated abundance (ea) in particular regions within the Carpathian range of *Rhinolophus euryale* (see text for details). Legend: w – winter period, s – summer period

the central part of Romanian Banat (Munții Almăjului and Munții Semenic Mts.; Fig. 1). Considering the lack of larger limestone layers and suitable caves in this region (cf. Bleahu et al. 1976, Orghidan et al. 1984), the absence of this bat is not surprising there. Besides some less important roosts in the Semenic Mts. (e.g. the caves of Peștera Găurile lui Miloi, Peștera cu Apă din Cheile Gârlăștei, and Peștera Lilieciilor din Cheile Carașului), the only noteworthy roost is known from the southern part of the Almăjului Mts. near the Danube, where an abundant nursery colony was reported from the Peștera Gura Ponicovei cave in 2002 and 2003 (900–1500 individuals; Murariu et al. 2004). However, rather intensive inspections of this cave during the last decade have not confirmed the existence of this colony (Uhrin et al., unpubl. data).

Transylvania. In western Romania, records of *R. euryale* are concentrated to several sections of the Apuseni Mts. This region is known to be the richest in karst phenomena in Romania (cf. Bleahu et al. 1976, Orghidan et al. 1984; Figs. 1, 2) and thus, it possesses rich availability of roosts for cave dwelling bats. The area is, among all identified groups of the Carpathian records, geographically the most extensive (Table 2), however, the prevailing number of sites is concentrated to the northwestern part of the area, to the Pădurea Craiului Mts. as well as to the Trascău Mts. in the northeast (cf. Bücs et al. 2012). This region is separated from the southern group of *R. euryale* records by the Timiș river valley and by the rather high Poiana Ruscă Mts., giving a distance of some 40 km only. In the Românești cave (48° 47' N), situated at the northern edge of the Poiana Ruscă Mts., the southernmost record of the species in Transylvania was documented. In the Zarandului and Metaliferi mountain chains only a few records of *R. euryale* were made (Dumitrescu et al. 1963, Barti 2005, Bücs et al. 2012). In the Peștera Igrita cave (47° 01' N) situated in the Pădurea Craiului Mts., *R. euryale* reaches the northernmost margin of the Serbian-Romanian distribution range (cf. Topál 1954, Borda 2002). The species reaches the easternmost occurrence point in the whole Carpathians in the limestone region of the Turzii Gorge in the Cluj District (the Cetățuia Mare and Cetățuia Mică caves; 23° 40' E). Although one record situated more eastward was reported from Romania, from the Piatra Craiului Mts. in 2000 (Szántó 2000), credibility of this report is rather limited. Until any further data are provided and mainly, with respect to the known pattern of *R. euryale* distribution in Romania, we tentatively consider this record as doubtful. The only known synanthropic roost of a nursery colony in an attic in Romania was found in a church in Moldovenești, the Trascău Mts. In Southern Carpathians and Transylvania, *R. euryale* occurs at most of the sites in sympatry or even syntopy with its congener *Rhinolophus blasii* Peters, 1866 (e.g. Kryštufek & Petrov 1989, Paunović & Stamenković 1998, Paunović et al. 1998, Bücs et al. 2012).

While the latter two groups of records are in direct connection with the core range of the species distribution in the Mediterranean (Gaisler 2001) and the populations most probably communicate with each other, the other three groups of records of *R. euryale* are situated at the northern margin of the Pannonian Lowland in Hungary and Slovakia, far from the continuous species range. These groups are separated from the two southern groups of the Carpathian records (Southern Carpathians, Transylvania) by the extensive steppes of Pannonia by about 140 km of aerial distance and clearly represent an island of occurrence out of the Mediterranean arboreal zone. Although an impact of such isolation on the population structure has not been studied in detail, the geographical separation was emphasised by several authors (Uhrin et al. 1996a, 2012, Schober 1998, Dietz et al. 2009b) and led to a wide research interest in these populations (see Miková et al. 2012). The area of these three spots of occurrence is geographically rather limited and covers some 6,000 km² only. In the northern part of this area, the highest density of sites of *R. euryale* records was documented, considering the whole Carpathian range (Fig. 1, Table 2).

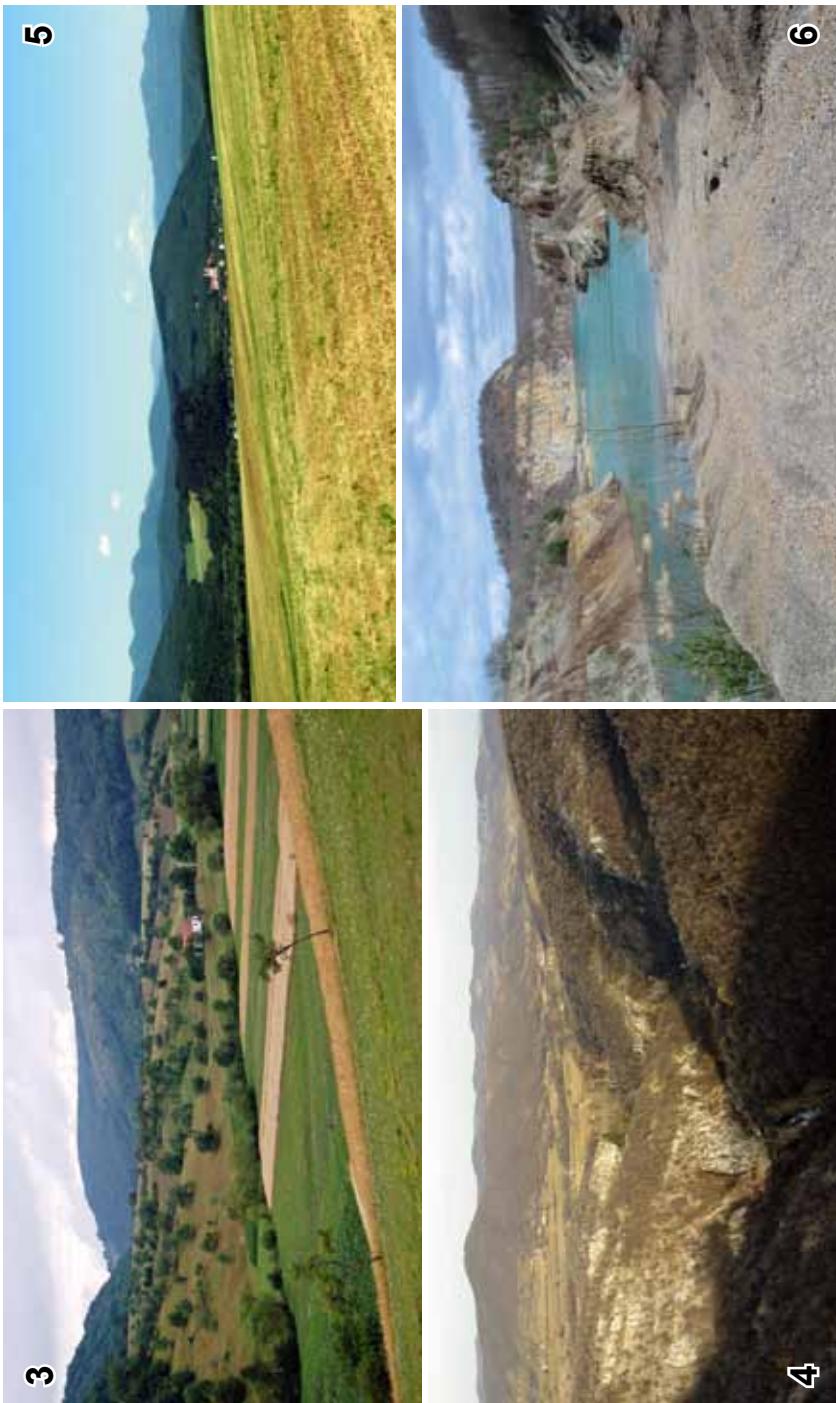

Bükkvidék Region. This region of *R. euryale* occurrence is situated close to the northern margin of the Pannonian Lowland. Geographically, the records come from three mountain ranges in total; the Bükk, Mátra and Tokaj-Zempléni-hegyvidék Mts. (Fig. 1). Relatively the highest number of records of *R. euryale* has been documented in the karst landscape of the Bükk Mts., where more than 40 sites are available (e.g. Vásárhelyi 1939, 1942, Czájlik 1986, Dobrosi 1994, Boldogh 2008). Almost all roosts of *R. euryale* found in these mountains were situated in caves; several noteworthy hibernation sites (e.g. the Kólyuk-barlang and Vár-tetői-barlang caves) as well as roosts of large nursery colonies (e.g. the Kecske-lyuk, Herman Ottó-barlang caves) are available there. The only exception in this region is a nursery colony roost in a church attic in Bánhorváti, where a large colony has been registered since 2008 (Table 3). In the Mátra Mts., only one site of summer occurrence has been documented, from the Antal-taró mine; similarly, only one site has been registered in the Tokaj-Hegyalja Mts., where the species has been found to hibernate in the Bomboly-bánya mine near Mág (Bihari et al. 2000).

Gemer-Turňa / Gömör-Torna Region. In this region, the highest number of record sites of *R. euryale* has been documented so far, considering its whole Carpathian range. A comprehensive evaluation of distribution of *R. euryale* in this area has already been published previously (Uhrin et al. 1996a, Boldogh 2006); the recent review of records (Fig. 1) shows a very similar geographical picture to those given by the latter authors. The record sites are concentrated to a small area of ca. 2,500 km² (Table 2) and are more or less evenly distributed over the whole region. Most of the sites are situated in the large limestone areas of the Slovenský kras Mts. (Slovak Karst) and of the Aggtelek-Rudabányai-hegyvidék and Aggteleki-karszt Mts. From the latter region, the most abundant aggregation of *R. euryale* within the whole Carpathian range is known, from the Baradla cave (Hungary) comprising some 4,500 bats (Fig. 12). In the Gemer-Turňa / Gömör-Torna region, *R. euryale* reaches the northernmost known occurrence within its whole distribution range, approaching 48° 42' N. Several *R. euryale* records were reported at this latitude (e.g. the Šarkanica cave, record in *S. aluco* diet; the Adam mine and the Dielik railway tunnel, hibernacula; the Betliar castle attic, nursery; Uhrin et al. 1996a, Matis 2002c) and all these sites are situated on southern slopes of rather high mountains (e.g. the Muránska planina, Volovské vrchy and the Revúcka vrchovina Mts.). Most probably, the species is unable to cross high altitudes of these mountain ranges. Three other records have been reported from Slovakia, situated more northwards from the above mentioned latitude (they are not shown in the maps in Figs. 1 and 2; for positions of these records see the map by Uhrin et al. 1996a: Fig. 3A); we consider all these records questionable. These records were reported from regions situated too far from the currently known species

range (Pružinská jaskyňa cave; Zajonc 1960) and/or from climatically very different regions, the Nízke Tatry Mts. (Lower Tatra Mts.). From the latter mountains, the records of *R. euryale* have been reported from two sites. In ca. 1933, several individuals of *R. euryale* were collected in the Demänovské jaskyne caves ($49^{\circ} 00' N$) (Gaisler 1956); six appropriately labelled specimens are still deposited in the collections of the National Museum, Prague, Czech Republic. However, in the same period (1932), the species was also collected in the Domica cave by V. J. Staněk, then a volunteer in the museum (see e.g. Staněk 1932) and by V. Benický (caretaker of the Domica cave), and the mislabelling of the former specimens thus cannot be excluded. The second record site in the Nízke Tatry Mts. is the Pustá jaskyňa cave, from which a finding of *R. euryale* was

Karapandžić). 5 – extensive deciduous forests in vicinity of the Jasovská jaskyňa cave (under the stone in the centre of the picture) and Lásrov Monastery, where ca. 500 individuals of *R. euryale* form a nursery colony in the loft space and a transient aggregation in the cave, Slovakia (photo by M. Uhrin). 6 – mining landscape in surroundings of the Rudabanya village, where a nursery colony of ca. 1,500 individuals *R. euryale* occurs in the Andrássy-bánya Mine (photo by S. Boldogh).

reported by Rybář (1980) from a Holocene bat thanatocoenosis. The specimen from the latter site was recently revised; a skull of an adult individual is deposited in the Museum of East Bohemia, Hradec Králové, Czech Republic. Anyway, this record indicates more extensive range of distribution of *R. euryale* in Europe over the Holocene, since the Boreal period (see e.g. Horáček 1995); however, the Recent occurrence of the species in the northern slopes of the Nízke Tatry Mts. where the Pustá jaskyňa cave lies, is quite unlikely (see also Bačkor et al. 2010).

While some roosts localised in the Gemer-Turňa / Gömör-Torna region are known for a very long time and also, they are under long-term monitoring (e.g. the Baradla barlang and Domica caves; Dudich 1930, 1932, Kettner 1932, Štěpánek 1936, 1939, Boldogh 2006), some other important roosts have been discovered only recently. This is certainly true for example for the mining regions in the Revúcka vrchovina Mts. in central Slovakia or for the vicinity of Rudabánya in northern Hungary (e.g. the Bradlo and Andrásy-bánya mines; Table 3, Figs. 6, 10, 11) or for some roosts in attics or in aboveground rooms in buildings, e.g. the Jasov monastery, the churches at Silická Jablonica (Slovakia), Szinpetri and Perkupa (Hungary), and/or an abandoned building near Szalonna in the Csehi-hegy Mts. (Hungary).

Dunazug-heggyidék Region. Records of *R. euryale* in the Budai-Hegység, Gerecsevidék, Északi-Bakony, Pilis-hegység and Vértes-hegység Mts. are the westernmost occurrence sites in the Carpathian region (comprising less than twenty sites in total) and represent the only region outside the arch of the Carpathians. This population is the only inhabiting the right side of the Danube in central Europe; it reaches its westernmost point in the Inotai karsztvíz-akna ürege cave ($18^{\circ} 11' E$; Paulovics & Juhász 2008) and *R. euryale* was recorded there only once. This locality is isolated from other sites of the respective region by a distance of ca. 40 km (Fig. 1). This conspicuous occurrence spot can be explained as a result of serious human disturbance which dispersed the colony from the most important hibernaculum, situated in the Pisznice-barlang cave (see Paulovics & Juhász 2008). All other localities are situated more closely to the Danube, at the distance of ca. 20 km from the closest mountain part of the Carpathians, the Börzsöny Mts. These sites were formerly known as noteworthy bat roosts, first documented in 1955 and 1988 respectively; in both caves, very rapid declines of the numbers of roosting bats were observed (Juhász 1994, 2007, Molnár 1997). This situation resulted in a special translocation project in order to strengthen this relic population (Paulovics & Juhász 2008, Juhász et al. 2009). Within this project, a long distance (>180 km) translocation of individuals has been repeatedly conducted since 2008. The bats were captured at the beginning of the hibernation period in a cave roost at Rudabánya (N Hungary) and translocated to the Pisznice-barlang cave.

Roosts and habitats

Rhinolophus euryale is traditionally considered to be a strictly cave-dwelling bat in its whole distribution range, using this roost type in all periods of its life cycle (e.g. Paunović & Stamenković 1998, Gaisler 2001, Benda et al. 2003, Kryštufek 2007, Koselj 2009). In the Carpathian part of the species range, caves still remain the most frequently selected roosts in all five regions (Fig. 2, Table 3). The bats use caves as hibernation roosts, nursery colony roosts or as shelters of pre-hibernation aggregations (Figs. 7–10, 15). According to Topál (1962), the sex ratio is normally more or less balanced in maternity roosts during summer. But within the whole Carpathian range one summer aggregation/roost has been identified, where only males were present – the Pećina Bela Sala cave, Serbia, where 40–120 male individuals were aggregated in a mixed colony of *R. euryale* and *R. blasii*. Since the early 1990s, several roosts in man-made underground spaces (abandoned mines, railway tunnels and military bunkers) have been identified in the area under

Examples of roosts inhabited by *Rhinolophus euryale* in the Carpathians. 7 – entrance to the Pestera de la Tăsad cave, roost of a nursery colony of ca. 500 individuals of *R. euryale*, Romania (photo by Sz. Bücs). 8 – entrance to the Lazareva pećina cave, roost of a nursery colony of ca. 100 inds. and hibernaculum of ca. 1,500 inds. of *R. euryale*, Serbia (photo by B. Karapandža). 9 – view of the Jásav Monastery, large lofts of the building are used as a roost by nursery colonies of four bat species (*R. euryale*, *R. hipposideros*, *R. ferrumequinum*, *Myotis emarginatus*), Slovakia (photo by M. Uhrin). 10 – entrance to the Bradlo mine, roost of a mixed nursery colony of ca. 3,000 inds. of *R. euryale* and *Miniopterus schreibersii*, Slovakia (photo by L. Dluhošová).

study; among them several sites represent very important *R. euryale* roosts (Table 3). Occurrence of the species in several aboveground rooms in buildings was known from the 1950s and 1960s (the Golubačka tvrđava castle, Serbia, in 1958, and the Krásna Hôrka castle, Slovakia, in 1969); however, these roosts are rather cave-like spaces and cannot be considered as real signs of a tendency to synanthropy in *R. euryale*. Nevertheless, the real process of synanthropisation in this species started rapidly in the 1970s, when the first individuals of *R. euryale* were found in attics of several buildings in Slovakia (Horáček & Zima 1979, Horáček et al. 1979, Horáček & Červený 1985). This roost type was very rare within the whole species range (Gaisler 2001); while in the period before 1974 all known nursery colonies were known solely from caves, nowadays nursery colonies consisting of numerous individuals have been recorded in three countries of the Carpathian species range (Table 3, Figs. 2a, 14) and the attic roosts represent 26.3% of all known roosts of nursery colonies in these countries. In Hungary, five attic roosts of nursery colonies have been documented and the church at Bánhorváti is the most noteworthy among them (up to 400 individuals of *R. euryale* at maximum). In addition, an aboveground roost in a building, where more than 700 individuals are present, has been discovered in the Csehi-hegy Mts. near Szalonna (Fig. 13). Solitary individuals in an attic roost in Romania were observed first in 2008 (Willemsen & Thomassen 2009), followed by the discovery of a more numerous colony in 2012 (more than 200 individuals in the church at Moldoveneşti). While this tendency to the shift of the roosting strategy in *R. euryale* could be now considered as a common trend in its Carpathian range, similar records in other parts of the species range are very rare. Few individual observations are available from Italy (D. Scaravelli, in litt.), Slovenia (Kryštufek & Donev 2005, Koselj 2009) and Bulgaria (Benda et al. 2003).

The altitudinal range of the distribution of *R. euryale* in the Carpathian region is 73–925 m a. s. l., however, the largest proportion of the record sites was found between 200 and 600 m a. s. l. (Fig. 16). The most elevated site is the Šarkanica cave (925 m a. s. l.) on the southern slope of the Muránska planina Mts., central Slovakia, where a skeleton remain was documented from an owl pellet. The most elevated roost of *R. euryale* is the hibernaculum in the Peștera Poarta lui Ionele cave (848 m a. s. l.) in the Bihor Mts. in Romania. In Serbia, nursery roosts have been mostly recorded at significantly higher altitudes than hibernacula. The surroundings of the roosts are a predominantly mosaic-like landscape with deciduous forests (e.g. with tree genera *Quercus*, *Fagus*, and *Carpinus*), disconnected by various, more or less extensive agricultural fields (Figs. 3, 5). Most of the sites are in limestone landscapes, with dramatic relief dynamics, rocky slopes and cliffs, karst phenomena as well as relevant bush-like vegetation cover (Fig. 4). The landscape structures observed in the Carpathian region conform with the data by Goiti et al. (2003, 2008) and Russo et al. (2002, 2005), indicating the structured forests to be the preferred foraging habitats of *R. euryale* in the Mediterranean. The same is also suggested by a study of foraging activity in *R. euryale* conducted in the Slovakian Carpathians (Miková et al. 2012).

Movements and abundance

The Mediterranean horseshoe bat is considered to be a sedentary species, showing strong roost philopatry and undertaking only short-distance movements (up to 50 km on average) between summer, winter and transient period roosts (Gaisler 2001, Hutterer et al. 2005, Dietz et al. 2009a). Limited recovery data from the area of the Carpathians (Tables 4, 5) are based on records of individuals banded mostly in the period 1950–1970 (Topál 1962b, Gaisler et al. 2003) on the Slovak-Hungarian transition area. Anyway, following the general recommendations (cf. Dietz et al. 2006), marking of this species by metal rings has been recently limited to special purposes and projects only (Paunović 1998, Fulín & Matis 2007, Paulovics & Juhász 2008, Juhász et al. 2009).

Recovery rate observed in the Carpathian region is quite low (Table 4) and the recaptures are related to movements within a locally limited group of roosts, probably used by local populations as the sites with a certain tradition. The distances of the movements were small (0.5–16.7 km) and document the relations between the nursery colony roosts, hibernacula and/or transient roosts, see e.g. the Miskolc-tapolcai-tavas barlang and Vár-tetői-barlang caves; the Ardovská jaskyňa and Líščia diera caves; the Jasovská jaskyňa cave and the Jasov Monastery; the Hajdučka pećina and Lazareva pećina caves. In the core distribution range in the Mediterranean, the distances between a hibernaculum and a summer roost were found to be larger, with the maximum aerial distance of 58.8 km in Bulgaria (Dietz et al. 2009a). Only exceptionally, longer movements (up to 134 km) were observed in Italy and France (Heymer 1964, Dinale 1967).

The highest longevity in the Carpathian range, defined as the period between banding and recapture, was 4,959 days in males and 3,941 days in females with the average of 993 days for both sexes (Table 4). These maximum ages documented (13 years, 7 months for a male and 10 years, 9 months for a female) conform to the maximum longevity known so far, 13 years, see Crucitti (1976).

In each of the delineated sub-ranges (group of records) of the species within the Carpathian region (Fig. 1), *R. euryale* creates at least one abundant nursery colony in a traditional roost (e.g. the Ljubinkova pećina cave, the Bradlo mine, the Jasov monastery) and one abundant hibernaculum (e.g. the Baradla or Lazareva pećina caves), surrounded by satellite roosts of various types used in various seasons (e.g. roosts of transient pre- and/or post-hibernation aggregations or of single individuals; e.g. Gaura Burči cave, Mandina pećina cave, Domica cave). Thus, the particular

populations could be assumed to create the metapopulation structure in all respective regions. Koselj (2009) estimated that the whole population from south-eastern Slovenia represents a single large colony using one principal nursery and one hibernation roost, and several adjacent satellite shelters. Similar metapopulation structure is known in the congeneric species, *R. ferrumequinum* (Schreber, 1774), see Bihari (2001). This arrangement of intra-population relations could result in population fragmentation and furthermore, to the reduction of genetic variation. This state was already documented in an isolated population of another congener and the closest relative, *R. mehelyi* Matschie, 1901, in Romania (Dragu & Borissov 2011).

Considering the supposed metapopulation structure, a strong philopatry and sedentary characteristics of local populations, supported by the available banding evidence, it is possible to estimate total abundance of the particular populations (Table 2). In the Slovak-Hungarian transition area, where such estimation could be based on several simultaneous censuses, *R. euryale* abundance is estimated at 5,000 individuals at maximum in the Baradla-Domica cave system

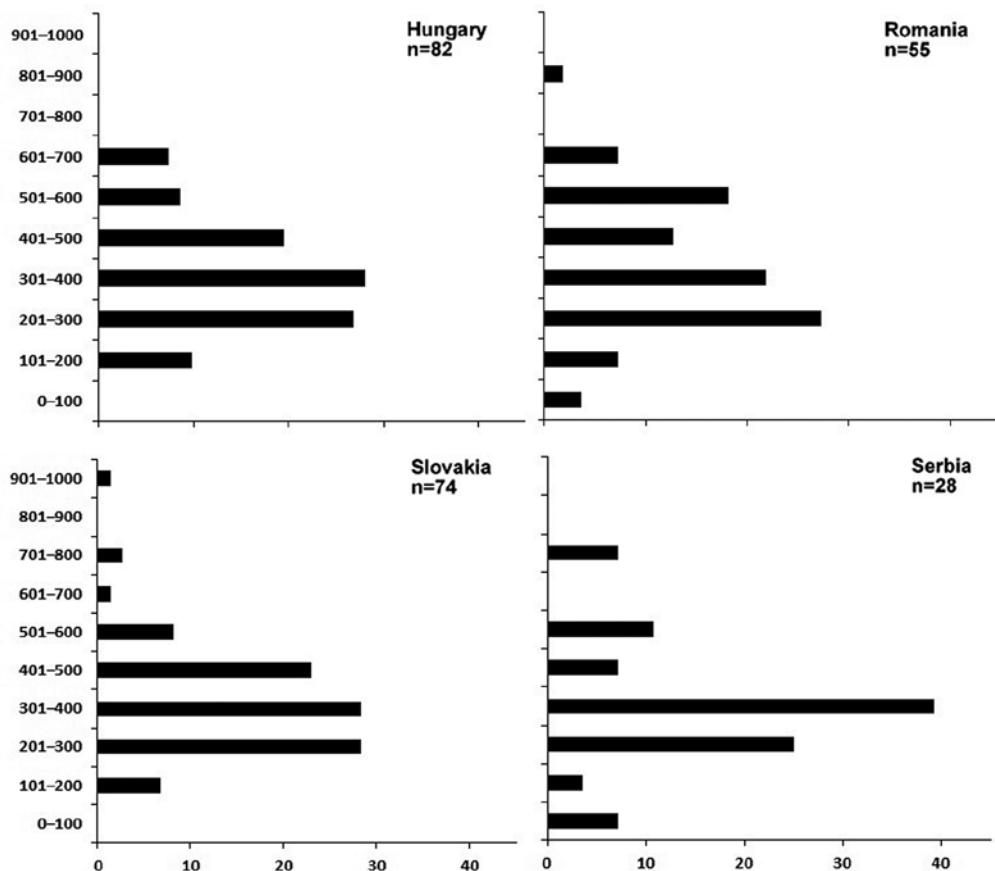

Fig. 16. Altitudinal distribution of the known localities with presence of *Rhinolophus euryale* in the Carpathian region expressed as percentage of localities (x axis) in a particular altitudinal range (y axis; m a. s. l.).

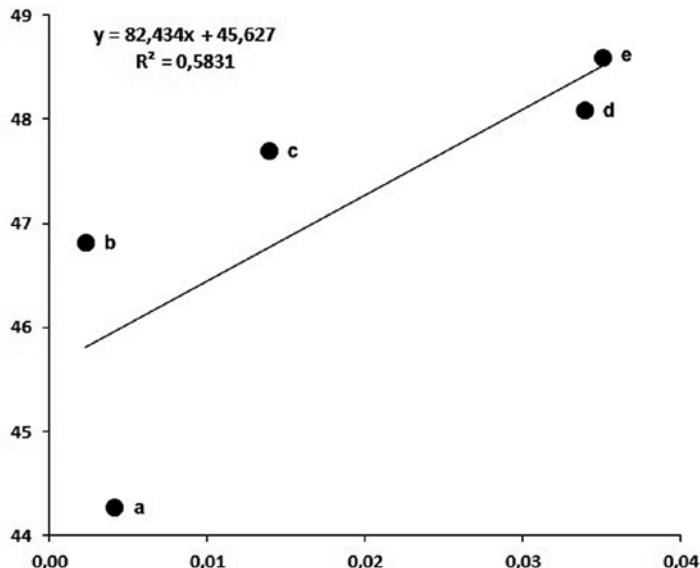

Fig. 17. Relationship between site densities (sites per km^2 , x axis) and latitude (y axis) in subpopulations of *Rhinolophus euryale* in the Carpathian region. a – Transylvania, b – Southern Carpathians, c – Dunazug-hegyvidék Region, d – Bükkvidék Region, e – Gemer-Turňa / Gömör-Torna Region (see Table 2 for exact density values).

(Miková et al. 2012). Thus, the abundance of *R. euryale* in the whole Carpathian system could be estimated at some 30,000 individuals only. Density of the documented roost sites varied little among the regional groups of localities (Fig. 1, Table 2) and generally, it increases along a cline from south to north (Fig. 17). This pattern could be interpreted as a function of geographically limited opportunities of roosts with suitable microclimatic conditions at the northern margin of the range. Thus, the species is concentrated there to a smaller territory compared to the situation in the Southern Carpathians or in the Mediterranean of the European peninsulas, where *R. euryale* is widespread. On the other hand, different levels of bat surveillance in the respective countries should also be considered.

In conclusion, the range of *Rhinolophus euryale* in the Carpathian region is limited to its warmest parts with the record sites divided into five separate regions. These regions are bounded by large river valleys, extensive lowlands and basins, and higher mountain ranges, which the species is probably unable to cross. The southern part of the range of *R. euryale* in the Carpathian region is directly connected with the core Mediterranean range and the species largely occurs there in sympatry / syntopy with *Rhinolophus blasii*. On the other hand, the northern part of the range of *R. euryale* in the Carpathian region is isolated and creates an island of the species occurrence separated by the vast area of Pannonia. Within the delineated range subdivisions, the species seems to be sedentary and perhaps shows the pattern of metapopulation structure organised around several and traditionally used unique and populated roosts (but further research on this topic is needed – see e.g. Dietz et al. 2009 vs. Bihari 2001). Compared to the situation in the core species range, *R. euryale* uses a more diversified roost strategy in the Carpathian region with a pronounced tendency to synanthropy in the reproduction period.

Appendix

Review of records of *Rhinolophus euryale* from the Carpathian region

List of records of *Rhinolophus euryale* in the Carpathians is arranged alphabetically by countries and site names within geomorphological / geographical units (Marković 1980, Mazúr & Lukníš 1980, Marosi & Somogyi 1990, Mândruț 2006). After the site name, the district name, altitude [m a. s. l.] and coordinates [WGS84] are given in parentheses, followed by date and description of the record; published data are simplified as a site name along with the reference (see explanations below). Where not specified, the record represents an observation; when a collection abbreviation is given, the collected specimens are available.

Abbreviations. ind. – individual (sex indeterminate); f – female; m – male; a – adult; s – subadult; j – juvenile; L – female in lactation; G – pregnant female; C – nursery colony; det. – a bat call recorded using ultrasound detector; net. – bat individual/s netted; OW – owl pellets (*Sa* – *Strix aluco*, *Ta* – *Tyto alba*); OS – osteological record; S – summer record (period between 1 April – 31 October); W – winter record (period between 1 November – 31 March); *Mema* – *Myotis emarginatus*; *Mschr* – *Miniopterus schreibersii*; *Rbla* – *Rhinolophus blasii*; *Reur* – *R. euryale*; *Rfer* – *R. ferrumequinum*; *Rmeh* – *R. mehelyi*; RBPA – Romanian Bat Protection Association; GUC – Gödöllő University Collection (Gödöllő, Hungary); HNHM – Hungarian Natural History Museum (Budapest, Hungary); NHMB – National History Museum (Belgrad, Serbia); PMS – Slovenian Museum of Natural History (Ljubljana, Slovenia); ANPI – Aggtelek National Park Directorate (Hungary); GBTE – Gerecse Speleological and Nature Conservation Association (Hungary).

Dobrosi); 23 February 2012: 1 m dead in a building near entrance (S. Boldogh); 27 February 2012: 1577 inds. in the Morea Hill (S. Boldogh, M. Juhász, E. Domina, Z. Hegyi); 27 February 2012: min. 100 inds. in the main tunnel (S. Boldogh, M. Juhász, E. Domina, Z. Hegyi); 19 March 2012: ca. 20 inds. in the Morea Hill (S. Boldogh, E. Miková); 19 March 2012: min. 10 inds. in the main tunnel (S. Boldogh, E. Miková); 5 September 2012: 1 f, 1 m (S. Boldogh); 24 September 2012: 20 inds. (S. Boldogh, K. Lear); 5 November 2012: 1801 inds. in the Morea Hill (S. Boldogh); 12 November 2012: 3563 inds. in the Morea Hill (S. Boldogh, T. Visnyovszky); 17 November 2012: 3558 inds. in the Morea Hill (S. Boldogh, E. Miková, M. Uhrin); 27 November 2012: 4651 inds. in the Morea Hill (S. Boldogh, E. Miková, M. Uhrin). – **Béke-barlang cave** (Aggtelek, 337 m, 48.5° N, 20.5° E), S, W (Boldogh 2006, 2007c); 7 February 2007: 6 inds. (S. Boldogh, Z. Bihari, O. Somogyvári); 23 September 2010: 8 inds., 5 m, 3 f (S. Boldogh); 9 February 2012: 1 ind. (S. Boldogh). – **Danca-barlang cave** (Égerszög, 320 m, 48.4° N, 20.6° E), 14 March 2012: 11 inds. (S. Boldogh, Á. Szabó); 3 October 2012: 1 m, 1 f (S. Boldogh). – **Jósvafő** (280 m, 48.5° N, 20.5° E), 20 September 2012: 1 f in ANPI appartments (S. Boldogh). – **Kossuth-barlang cave** (Jósvafő, 207 m, 48.5° N, 20.6° E), S (Boldogh 2006). – **Magas-tetői-barlang cave** (Szögliget, 430 m, 48.6° N, 20.7° E), S (Boldogh 2006, 2007b); 13 February 2004: 1 ind. OS (S. Boldogh, Š. Matis, T. Burinda, P. Pjenčák); 10 September 2007: 2 m net. (S. Boldogh); 9 September 2008: 1 m net. (S. Boldogh); 4 October 2011: 10 inds. (S. Boldogh, I. Mihalik, Á. Szabó). – **Meteor-barlang cave** (Bódvaszilas, 415 m, 48.6° N, 20.7° E), W (Boldogh 2007b); 12 January 2012: 5 inds. (S. Boldogh). – **Szelce-puszta**, touristic cottage (Szin, 390 m, 48.5° N, 20.6° E), 5 July 2011: C 25–30 inds. (S. Boldogh); 9 August 2012: 3 inds. (S. Boldogh). – **Szinpetri, church** (180 m, 48.5° N, 20.6° E), 9 August 2012: 2 inds. (S. Boldogh).

Budai-hegység Mts.: **Bátori-barlang cave** (Budapest, 439 m, 47.5° N, 19.0° E), S, W (Méhely 1900); 28 July 1919: 1 ind. a, 1 f, 1 ma (HNHM). – **Farkas-völgy** (Budapest, 460 m, 47.5° N, 19.0° E), W (Czajlik 1986). – **Hárs-hegyi-barlang cave** (Budapest, 409 m, 47.6° N, 19.0° E) (Méhely 1900). – **Remete-barlang cave** (Budapest, 286 m, 47.6° N, 19.0° E), January 1900: 1 ad (HNHM, T. Kormos). – **Solymári ördöglyuk cave** (Solymár, 353 m, 47.6° N, 19.0° E), W (Méhely 1900, Topál, 1954, Paulovics & Juhász 2008).

Bükkelja Mts.: **Fecske-lyuk cave** (Miskolc, 164 m, 48.1° N, 20.7° E), S (Gombkötő et al. 2007). – **Herman Ottó-barlang cave** (Miskolc, 236 m, 48.1° N, 20.6° E), S (Vásárhelyi 1930, 1939, 1942; Dobrosi 1994, Gombkötő et al 2007); 22 June 2007: C 2800 inds. (P. Gombkötő); 8 September 2009: 5 inds. (P. Gombkötő); 12 September 2012: 1 f (P. Estók). – **Miskolc** (250 m, 48.1° N, 20.7° E), 12 September 1954: 1 fj, 1 fs (Anonymous). – **Miskolctapolcai tavasbarlang cave** (Miskolc, 130 m, 48.1° N, 20.7° E), S (Vásárhelyi 1939, Topál 1956, 1962, Beron 1965, Czajlik 1986); 17 July 1954: 1 ma, 10 fa, 12 mj, 15 fj, 1 m, 1 f (HNHM, G. Topál); 18 July 1954: 5 fa, 2 mj, 2 inds. a (HNHM, G. Topál); 4 July 1955: 1 ma, 1 mj, 2 fa, 1 fj, (HNHM, G. Topál); 6 July 1955: 4 fj, 2 ma, 2 fa (HNHM, G. Topál); 20 July 1956: 1 ind. j, 1 mj, 1 fa (HNHM, G. Topál); 23 July 1956: 3 fj, 1 ind. j (HNHM, G. Topál); 6 July 1958: 1 ma (cavers' data); 20 July 1958: 1 ma, 3 f (cavers' data); 27 July 1958: 1 fa (cavers' data); 6 August 1958: 1 ma (cavers' data). – **Nagykőmázssa-oldali-zsomboly cave** (Miskolc, 332 m, 48.1° N, 20.7° E), 9 September 1999: 150–200 inds. (P. Gombkötő, G. Ferenczy); 3 August 2003: 1 ind. (P. Gombkötő). – **Viktória-barlang cave** (Miskolc, 189 m, 48.1° N, 20.7° E), S (Gombkötő et al. 2007). – **Zsendice-barlang cave** (Kács, 366 m, 48.0° N, 20.6° E) (Dobrosi 1994).

Bükklába Mts.: **Bánhorváti, church** (180 m, 48.2° N, 20.5° E), 21 June 2006: C 30 inds.; 5 July 2007: C 80 inds.; 23 July 2008: C 80 inds.; 30 July 2009: C 200 inds.; 20 July 2010: C 300 inds.; 11 August 2011: mixed C 300 inds. of *Rfer* and *Rfer*; 11 July 2012: C 400 inds. (all records P. Gombkötő).

Északi-Bakony Mts.: **Inotai karsztvíz-akna ürege cave** (Várpalota, 156 m, 47.2° N, 18.2° E), W (Paulovics & Juhász 2008).

Gerecsevidék Region: **Baits-barlang cave** (Bajót, 347 m, 47.7° N, 18.6° E), 26 April 2012: 4 inds. (M. Juhász, E. Domina). – **Bajói Büdös-lyuk cave** (Bajót, 234 m, 47.7° N, 18.6° E), W (Paulovics & Juhász 1998); 28 December 2011: 1 ind. (M. Juhász, B. Máté); 24 March 2012: 4 inds. (M. Juhász, Z. Polacsek); 26 April 2012: 10 inds. (M. Juhász, E. Domina); 31 May 2012: 10 inds. (M. Juhász, Z. Hegyi). – **Bajói Büdös-lyuk cave** (Bajót, 234 m, 47.7° N, 18.6° E), 1 June 1916: 1 m, 2 fa (HNHM, T. Kormos). – **Keselő-hegy II. triászbánya tárója mine** (Tatabánya, 232 m, 47.6° N,
